

EQUITY RESEARCH | SOVEREIGN WEALTH

Mubadala Investment Company

Portfolio strategy, sector allocation and valuation case studies across technology, healthcare, energy and financial services

By:	Bann Abushamah
Document	Equity research report
Date	August 2026
Subject	Mubadala Investment Company (Abu Dhabi sovereign investor)
Data as at	FY2025 results; market data July - August 2026
Case studies	GlobalFoundries WHOOP OMV AG Mubadala Capital
Methods	FCFF DCF, reverse DCF, trading comparables, mean-variance optimisation, Monte Carlo simulation, machine-learning classification
Deliverables	SQL warehouse, live Excel models, interactive dashboard

1. Executive summary

Mubadala Investment Company ended 2025 with assets under management of AED1.414 trillion (US\$385 billion), up 17% on the year, having compounded at 10.7% a year over five years and 10.3% over ten. It deployed US\$39 billion and realised US\$38 billion. Those four numbers describe a balance sheet that grew without needing new shareholder capital.

ASSETS UNDER MANAGEMENT US\$385bn +17% year on year	5-YEAR ANNUALISED IRR 10.7% 10-year: 10.3%	CAPITAL DEPLOYED 2025 US\$39bn +20% year on year	PROCEEDS 2025 US\$38bn +27% year on year
---	--	--	--

This report asks five questions and answers each with evidence built from scratch.

- 1. Is the portfolio concentrated?** Yes, and deliberately. The Herfindahl-Hirschman index of the disclosed asset-class mix is 2,734, which is formally 'concentrated'. The effective number of independent buckets is 3.7, not the five that the reported breakdown implies. Fifty-eight per cent of assets sit in private and alternative strategies, which is the illiquidity premium a sovereign investor with no redemption risk is uniquely able to harvest.
- 2. Is growth self-funded?** Yes. Proceeds covered 97 cents of every dollar deployed in 2025 and have averaged a recycling ratio of 1.01 over three years. Growth in the book came from performance and from realisations, not from a capital call on the shareholder.
- 3. Is the asset mix efficient?** Not in a narrow mean-variance sense, and that is informative rather than damning. The published mix carries roughly 1.02 percentage points more volatility than an efficient portfolio at the same expected return. Almost all of the gap is the 20% public-equity sleeve, which a pure return optimiser would not hold at all. That sleeve is the price of liquidity, and quantifying that price is the useful output.
- 4. What is technology worth to the strategy?** Semiconductors, AI infrastructure and AI-enabled healthcare recur across every one of the four investment platforms, not just inside a technology bucket. GlobalFoundries alone represents an enterprise value of US\$25.4 billion; the CoolIT realisation into a US\$4.75 billion transaction shows the AI-infrastructure theme being monetised, not just accumulated.
- 5. Are the individual assets fairly valued?** Mixed, and the differences are instructive. Our base-case discounted-cash-flow valuation of GlobalFoundries is \$35.07 a share against a market price of \$50.01; inverting the model shows the market requires a steady-state operating margin of 33.4% against 12.1% today. OMV screens close to fair value at EUR56.42 against EUR54.60, but free-cash-flow cover of its dividend has collapsed from 6.0 times to 1.3 times in four years. WHOOP's US\$10.1 billion Series G requires revenue to compound at 34.8% a year for a decade.

Key finding:

Across three of the four case studies the interesting question was not what *is it worth* but *what does the price already assume*. Inverting a valuation model turns an argument about opinions into a statement that can be tested against evidence. That is the analytical habit this project is built around.

2. The institution and its mandate

Mubadala is Abu Dhabi's sovereign investor. Its mandate, in the company's own words, is to deliver **sustainable, risk-adjusted returns** for its shareholders, the Government of Abu Dhabi, while supporting the **diversification of the domestic economy away from hydrocarbons**. Those objectives are always always aligned, and much of what looks unusual about the portfolio is the visible seam between them.

2.1 Four platforms, one balance sheet

The business is organised around four global investment platforms. Understanding them matters because the same sector appears in more than one, with a different objective each time.

Platform	Chief executive	What it is actually for
UAE Investments	Dr Bakheet Al Katheeri	The national mandate. Builds homegrown champions and industrial clusters in energy, metals, aerospace, technology, healthcare, real estate and infrastructure. Success here is measured partly in GDP contribution, not only in IRR.
Private Equity	Camilla Languille and Luca Molinari	Global direct buyouts and late-stage growth equity, principally North America and Europe with growing Asia exposure. This is where the return-seeking capital lives.
Credit and Special Situations	Hani Ahmad Barhoush	Private debt, GP stakes, secondaries and opportunistic capital-structure solutions. Also home to Mubadala Capital, the asset-management subsidiary running about US\$30bn across balance-sheet and third-party vehicles.
Real Assets	Khaled Al Shamlan Al Marri	Real estate and infrastructure chosen for steady, visible cash flow across cycles. The ballast.

2.2 What the credit rating tells you

Mubadala's issuing entity carries long-term ratings of Aa2 from Moody's and AA from both S&P Global and Fitch, all with stable outlooks. Those ratings explicitly reflect the support of the sole shareholder rather than the standalone credit of the portfolio. The practical consequence is a cost of debt far below what an equivalently levered private fund would pay, which is a structural competitive advantage when bidding for long-duration assets. It is also why the balance sheet can afford to be illiquid.

Why this section exists. A valuation is only as good as the understanding of the business behind it. Half the analytical mistakes in this project's first draft came from treating Mubadala as if it were a return-maximising fund. It is not. It is a return-maximising fund with a second mandate bolted on, and the second mandate explains most of the apparent inefficiencies.

3. Portfolio composition and sector allocation

3.1 Asset-class mix

Mubadala disclosed the following split for FY2025: private assets 42%, public markets 20%, real estate and infrastructure 17%, alternatives 16% and credit 5%. Applied to US\$385 billion of AUM, that implies roughly US\$162 billion in private assets and US\$77 billion in listed equities.

Portfolio by asset class, FY2025

Figure 1: Portfolio by asset class, FY2025. Source: Mubadala 2025 Annual Review.

The headline observation is illiquidity. Private assets plus alternatives account for 58% of the book. For a pension fund with monthly redemptions that would be reckless; for a sovereign investor with a permanent capital base and no liabilities to match, it is the whole point. Illiquidity is the one risk premium that cannot be arbitrated away by anyone who might need their money back.

3.2 How concentrated is it, really?

A five-way split looks diversified. Measuring it says otherwise. The Herfindahl-Hirschman index - the sum of squared percentage weights, the same statistic competition regulators use to assess market concentration - comes out at 2,734. Anything above 2,500 is classified as concentrated. Inverting the index gives an 'effective number' of 3.7 independent buckets rather than five.

How to read the HHI. If capital were spread perfectly evenly across five buckets, each would be 20%, the index would be $5 \times 20^2 = 2,000$, and the effective number would be exactly 5. The higher the index climbs above that, the more the portfolio behaves like a smaller number of larger bets. At 2,734 Mubadala is running roughly three and a half real positions, dominated by the private book.

3.3 Sector footprint

Mubadala does not publish a position-level portfolio. To analyse sector allocation we assembled a dataset of twenty named holdings from the company's own disclosures, four of them listed, and tagged each to a sector, a country and a platform. Every row carries an evidence grade so that a reader can see which facts are company-stated and which are drawn from press reporting. Sixteen of the twenty are officially confirmed.

Figure 2: Tracked holdings by sector, shaded by AI exposure. Source: author's dataset built from Mubadala disclosures.

Technology, financial services, and real estate and infrastructure each account for four of the twenty tracked positions. But counting positions understates technology's importance. Semiconductors sit inside the UAE Investments mandate through GlobalFoundries' Western fab footprint; AI infrastructure runs through MGX and the CoolIT realisation; AI-enabled healthcare arrives through WHOOP; and renewable-asset software arrives through Power Factors, which we have classified as technology but could equally be called energy. The theme is a spine running through the portfolio rather than a slice of it.

3.4 Geographic allocation

Figure 3: Geographic footprint of tracked holdings. Source: author's dataset.

Seventy per cent of tracked holdings sit outside the home market, with North America the largest single region at 35%. This is the two-mandate structure made visible: domestic capital is deployed to build national capability, international capital is deployed to earn a return, and the international book is the larger of the two. Mubadala describes itself as active in more than fifty countries.

4. Capital deployment and investment trends

Figure 4: Capital deployed versus proceeds, 2023-2025. Source: Mubadala 2025 Annual Review.

Deployment rose from US\$24 billion in 2023 to US\$39 billion in 2025, a 63% increase in two years. Proceeds rose from US\$27 billion to US\$38 billion over the same period. Dividing one by the other gives a recycling ratio: 1.13 in 2023, 0.94 in 2024 and 0.97 in 2025.

Year	Deployed (US\$bn)	Proceeds (US\$bn)	Net (US\$bn)	Recycling ratio
2023	24.0	27.0	(3.0)	1.13x
2024	32.0	30.0	2.0	0.94x
2025	39.0	38.0	1.0	0.97x

A ratio near 1.0 sustained across three years is the signature of a mature investment platform rather than a growing one. Mubadala is not scaling by adding capital; it is scaling by turning the portfolio over faster at a higher level of activity. That matters for the risk assessment: an institution that must sell to buy is exposed to exit markets closing, which is precisely what a 20% liquid sleeve and a fee-earning subsidiary are there to insulate against.

4.1 What the deal log actually shows

We logged nineteen announced transactions across 2025 and 2026 from Mubadala's own newsroom and annual review. Nine carry a disclosed value totalling US\$44.4 billion. Ten disclose no value at all.

Because more than half the transactions have no published value, any 'total deal value' figure built from public sources is a floor, never a total. This project reports the floor and labels it as such. Databases that quietly estimate the missing values produce a bigger, more impressive and less true number.

Announced	Transaction	Sector	Value (US\$m)
2026	CoolIT minority stake sold to Ecolab, KKR-led	Technology	4,750 (transaction value)

Announced	Transaction	Sector	Value (US\$m)
2025	ADIC indirect deployments	Multi-sector	19,061
2025	Al Maryah Island transformation	Real estate	16,338
2025	Tabreed - two largest ever transactions	Infrastructure	1,054
2025	Fortress strategic partnership	Financial services	1,000 (to be deployed)
2026	WHOOOP Series G participation	Healthcare	575 (round size)
2025	Nord Anglia Education stake	Education	600
2025	Mubadala Capital Co-Investment Fund I close	Financial services	550
2025	Barings global real-estate debt partnership	Real estate credit	500

The pattern in the undisclosed half is as informative as the disclosed half. Hornsea 3 offshore wind, the Greenlink interconnector, the Stonepeak container-leasing platform, the Aldar joint venture at Masdar City, the Tubacex energy-supply-chain venture and the Embraer aerospace agreement are all long-duration real assets or industrial partnerships. Mubadala is buying cash flows that are contracted, regulated or strategically protected, and it is doing so alongside partners - Apollo, KKR, Stonepeak, Equitix, Barings, Fortress - rather than alone. Co-investment is the operating model.

5. Case study 1 - Technology: GlobalFoundries

GlobalFoundries is a specialty semiconductor foundry listed on Nasdaq, in which Mubadala is the controlling shareholder with a stake widely reported at around 80% held through Mubadala Technology Investment Company. It is the largest single technology position in the group and the cleanest test of valuation discipline, because unlike most of the portfolio it has a daily market price to argue with.

SHARE PRICE	ENTERPRISE VALUE	REVENUE TTM	EV / EBITDA
\$50.01	\$25.4bn	\$6.84bn	12.1x
3 Aug 2026	market	EBITDA \$2.10bn	peer UMC 14.5x

5.1 Method and cost of capital

We built a five-year free-cash-flow-to-firm model. Cost of equity uses the capital asset pricing model with a 4.25% risk-free rate, a 5.0% equity risk premium and the observed five-year beta of 1.76, giving 13.05%. With gross debt of US\$1.72 billion against a US\$27.4 billion market capitalisation, the weighted average cost of capital is 12.55%. As a sense check, the published vendor estimate is 13.25% - close enough that the difference does not change the conclusion.

The revenue forecast starts from consensus, which puts three-year revenue growth at about 10% a year. We assume a cyclical recovery front-loaded into years two and three, fading to 5%. On margins we do not assume management delivers its stated plan in full: gross margin was 26.1% on a trailing basis against a public target of 40% by 2028 and 45% by 2030, and we model operating margin reaching 20% rather than the high-twenties that full delivery would imply.

Figure 5: GlobalFoundries valuation football field. Source: author's models.

5.2 Result, and the more interesting question

The base case values the equity at \$35.07 a share, 30% below the traded price. Comparable-company analysis at 11.0 to 17.0 times EV/EBITDA gives \$46 to \$69, a range that comfortably contains the market. Sell-side consensus sits at \$80.24.

Rather than declare the market wrong, we inverted the model and solved for the assumption that would justify the traded price. The answer is a steady-state operating margin of 33.4%, against 12.1% today.

What that number means. A 33% operating margin is roughly what full delivery of management's 45% gross-margin target for 2030 would produce. The market is not pricing today's foundry; it is pricing the successful execution of a six-year margin plan, plus the silicon-photonics, quantum and automotive content that sits behind it. Buying the shares at \$50 is an underwriting of execution, not a valuation call. Stating it that way makes the risk legible.

5.3 Evidence that the mix is already shifting

Figure 6: Change in GlobalFoundries revenue mix, 2023-2025. Source: company reported segment data.

Automotive silicon grew 34.8% between 2023 and 2025 and rose 6.6 percentage points as a share of revenue, while home and industrial internet-of-things fell 25.9% and lost 4.2 points. Smart mobile devices remain the largest end-market at 39% but are shrinking. This is a company actively rotating toward higher-content, longer-cycle silicon, which is consistent with the margin story - but the datacenter and communications line, the one most exposed to the AI narrative, is still only 11% of revenue and fell over the period. The optionality the market is paying for has not yet appeared in the reported numbers.

Peer selection - one exclusion, stated openly. Tower Semiconductor trades on 90.8 times EV/EBITDA after a 425% twelve-month re-rating. Including it in the peer median would not tell us what a foundry is worth; it would tell us what a momentum stock is worth. It is reported in the peer table and excluded from the applied range, and the exclusion is disclosed rather than buried. An unstated outlier exclusion is the most common way comparable-company analysis is quietly rigged.

6. Case study 2 - Energy: OMV AG

Mubadala holds 24.9% of OMV, the Vienna-listed integrated oil, gas and chemicals group, through Mubadala Petroleum and Petrochemicals Holding. It is a mature, cash-generative, cyclical asset with an 8.1% dividend yield - and it required three judgement calls that a mechanical model would have got wrong.

6.1 Three adjustments, each disclosed

1. **The beta is not credible.** OMV's observed five-year beta is 0.21, which would imply an integrated energy producer carries almost no systematic risk. The cause is mechanical: a free float of 141 million shares out of 326 million and a domestic index listing suppress measured covariance. We substituted a European integrated-energy sector beta of 0.90 and disclosed the swap. The effect is to raise the cost of equity to 8.70% and the weighted average cost of capital to 6.97%.
2. **Enterprise value contains large minorities.** Market capitalisation is EUR17.6 billion and enterprise value EUR24.2 billion, but net debt is only EUR2.8 billion. The residual - roughly EUR3.75 billion - is minority interest, because OMV fully consolidates Borealis and Borouge while owning less than all of them. Failing to deduct it in the equity bridge would have overstated value per share by about 25%.
3. **Reported earnings are not capitalisable.** Trailing twelve-month earnings per share of EUR7.20 include EUR1,303 million from *discontinued* operations. Applying a price/earnings multiple to that would value a business OMV no longer owns. FY2025 earnings of EUR3.11 are equally unusable in the other direction, having absorbed EUR497 million of write-downs. We used a three-year average of EUR3.96 as a mid-cycle proxy.

6.2 Result

The discounted cash flow values the equity at EUR56.42 a share against a market price of EUR54.60 - within 4%, which for a commodity business is as close to 'fairly valued' as a model gets. Normalised price/earnings comparables against Shell, TotalEnergies, Eni and BP give a range of EUR39 to EUR62 with a median of EUR49. Consensus sits at EUR61.

Figure 7: OMV valuation football field. Source: author's models.

6.3 The dividend is the real story

OMV yields 8.1%. The relevant question is not whether the shares are cheap but whether the distribution is funded by cash the business actually earns. We tested free-cash-flow cover across five years.

Figure 8: OMV free cash flow versus the cost of the dividend, 2021-2025. Source: company reported data.

Year	Free cash flow (EURm)	Dividend per share	Dividend cost (EURm)	FCF cover
2021	4,520	EUR2.30	750	6.03x
2022	4,815	EUR2.80	913	5.27x
2023	2,222	EUR2.95	962	2.31x
2024	1,943	EUR3.05	994	1.95x
2025	1,366	EUR3.15	1,027	1.33x

The finding: The FCF cover has fallen from 6.0 times to 1.3 times in four years while the dividend per share has been raised every single year. The payout is still covered - just. But the margin of safety has effectively gone, and one further leg down in refining or chemicals margins forces the distribution to be funded from the balance sheet or cut. For a shareholder like Mubadala, whose interest in this asset is substantially the cash it returns, that trajectory matters more than the two per cent of upside in the valuation.

7. Case study 3 - Healthcare: WHOOP

In March 2026 WHOOP, the AI-driven human-performance and health platform, raised US\$575 million in Series G funding at a US\$10.1 billion post-money valuation. Mubadala participated alongside the Qatar Investment Authority, Abbott, Mayo Clinic and Collaborative Fund, which led. Mubadala separately announced a UAE preventative-health and research partnership with the company.

POST-MONEY VALUATION \$10.1bn 31 Mar 2026	BOOKINGS RUN-RATE \$1.1bn exiting 2025	2025 BOOKINGS GROWTH +103% cash-flow positive	MEMBERS 2.5m+ \$440 revenue each
--	---	--	---

7.1 Why a normal DCF would have been dishonest

WHOOP is private. It publishes no accounts. Building a ten-year forecast from nothing and presenting the output as a valuation would be an exercise in laundering assumptions through arithmetic. So we ran the model backwards. The price a syndicate of sophisticated investors actually paid is a hard fact; what that price implies about the future is the thing worth calculating.

At a US\$10.1 billion post-money valuation on a US\$1.1 billion run-rate, WHOOP was priced at 9.2 times revenue, or 8.7 times excluding the cash just raised. The median listed healthcare platform in our reference set trades at 4.5 times sales, so the entry price is a 1.9-times premium to public comparables.

7.2 Solving for what the price assumes

Holding a required return of 18%, terminal growth of 3.5%, a ten-year horizon and free-cash-flow margins ramping from 4% to 20%, we solved for the revenue growth rate that reproduces the price paid.

The answer. Revenue must compound at **34.8% a year for ten years**, taking WHOOP from a US\$1.1 billion run-rate to roughly **US\$22 billion by 2035**, while free-cash-flow margins reach 20%. That is demanding. It is not absurd against 2025 bookings growth of 103% and a business that was already cash-generative. The investment question is therefore about the *durability* of growth, not its direction - and durability in consumer subscriptions is a churn question, which is the one metric not disclosed.

Figure 9: WHOOP scenario values against the price paid. Source: author's reverse-DCF model.

The scenario spread is wide and asymmetric in an instructive way. If growth fades to 12% and margins cap at 12%, the equity is worth about US\$1.0 billion - an 89% loss from the entry price. If platform economics take hold at 42% growth and 25% margins, it is worth about US\$24.6 billion. This is the shape of a venture position: a small probability of a very large outcome, funded by accepting a meaningful probability of near-total loss. Mubadala's participation is sized accordingly, as a minority in a syndicated round, which is the correct response to that payoff distribution.

7.3 Why this asset fits the strategy

- It is an **AI-data business wearing healthcare clothing**. Twenty-four billion hours of physiological data is the asset; the wrist strap is the collection mechanism. That is the same thesis as the group's semiconductor and AI-infrastructure positions, expressed in a different sector.
- The **UAE partnership converts a financial holding into a national-mandate asset**, bringing preventative-health capability onshore. One cheque serves both of Mubadala's objectives.
- Abbott and Mayo Clinic joining as strategic investors materially **de-risks the regulatory pathway** from consumer wellness toward clinical-grade prediction, which is where the durable margin would come from.

8. Case study 4 - Financial services: Mubadala Capital

Mubadala Capital is the group's wholly owned alternative asset manager. Mubadala's own website states that it manages approximately US\$30 billion in aggregate across balance-sheet investments and third-party capital vehicles, through four businesses: Private Equity, Brazil, Venture Capital and Solutions. That single figure is the only hard input available - everything else in this case study is a labelled assumption, and the output is a framework rather than a valuation opinion.

8.1 The question worth asking

Not 'what is Mubadala Capital worth' - nobody outside the group can answer that. The useful question is structural: *if it were listed, what would the market pay for the fee stream, and therefore how much value does the asset-management franchise add on top of the investment returns Mubadala earns anyway?*

Input	Value	Grade
Aggregate AUM	US\$30bn	Official - mubadala.com
Third-party share of AUM	60%	Author assumption
Blended management fee rate	1.20%	Author assumption
Implied management fee revenue	US\$216m	Derived
Fee-related-earnings margin	35%	Author assumption
Implied fee-related earnings	US\$76m	Derived
Private-company / control discount	25%	Author assumption

Figure 10: Implied value of the Mubadala Capital fee franchise. Source: author's model.

Benchmarked against Blackstone, Ares, Blue Owl and TPG on price-to-fee-revenue, and cross-checked on Blackstone's price/earnings multiple applied to fee-related earnings, the central estimate is US\$1.89 billion before discount and US\$1.42 billion after a 25% private-company discount - roughly 0.4% of group AUM.

Apollo excluded, and why. Apollo's reported revenue consolidates Athene's insurance premiums, which puts it on 2.1 times sales against a cohort clustered between 5 and 11 times. That is not a valuation signal, it is an accounting artefact. It is shown in the peer table and excluded from the applied range.

8.2 Why the structure matters more than the number

The number is soft. The structural point is not. Mubadala Capital converts third-party capital into a fee annuity that is valued on a multiple of earnings, sitting on top of the investment return earned on Mubadala's own balance sheet. Three consequences follow.

- **It extends reach beyond the balance sheet.** Third-party capital lets Mubadala underwrite transactions larger than its own equity cheque would allow, and take fees for the privilege.
- **It is counter-cyclical to realisations.** Management fees keep arriving when exit markets close. Given a recycling ratio near 1.0, that insulation has real value.
- **It is the only part of the group creating value independently of asset prices.** Everything else in the portfolio is a claim on the direction of markets. A fee stream is a claim on assets under management, which is a different and steadier thing.

9. Quantitative and AI analysis

9.1 Is the disclosed asset mix efficient?

We built an efficient frontier over the five disclosed asset classes using long-horizon capital-market assumptions. Mubadala publishes weights but not returns, volatilities or correlations, so those inputs are the author's and are stated explicitly in the model file. The conclusions below concern structure, not precision.

Figure 11: The disclosed mix against the efficient frontier. Source: author's optimisation.

On these assumptions the published mix has an expected return of 9.45% with volatility of 12.49%, a Sharpe ratio of 0.416. An efficient portfolio delivering the same return would carry 11.46% volatility - so the actual allocation is carrying about 1.02 percentage points of avoidable risk.

Almost all of that gap is the public-equity sleeve. The maximum-Sharpe portfolio holds **no** listed equity at all, replacing it with credit at 26% against an actual 5%. On a pure risk-return basis the 20% public allocation is not earning its place.

But that is not a criticism. A sovereign investor holds liquid assets so that a drawdown can be funded without selling private positions into a bad market. The optimiser cannot see that constraint because it has no concept of liquidity. What the exercise does is put a price on the insurance: roughly one percentage point of volatility, or about 0.5 percentage points of expected return. That is a number a board can debate. 'Is 20% public equity right?' is not.

Running the optimisation in reverse is more revealing still. If we assume the published weights are optimal and solve for the returns that would make them so, the implied expectations are: private 11.0%, public 10.0%, alternatives 8.4%, real estate and infrastructure 7.2%, credit 5.5%. Those are the beliefs an allocator must hold to justify this portfolio, and unlike the allocation itself they can be argued with directly.

9.2 Ten-year outlook under uncertainty

We simulated 50,000 ten-year paths for AUM using the disclosed 10.7% five-year return, an assumed 12.5% volatility, the observed US\$1 billion of annual net deployment, and Student-t shocks with five degrees of freedom so that the tails are fat in the way real markets are.

Figure 12: Ten-year AUM simulation, 50,000 paths. Source: author's Monte Carlo model.

Percentile	2035 AUM (US\$bn)	Implied CAGR
5th	559	3.8%
25th	819	7.9%
Median	1,058	10.6%
75th	1,360	13.4%
95th	2,004	17.9%

The median path crosses US\$1 trillion, and the probability of reaching that level by 2035 is 56%. Equally important is the downside: the median worst peak-to-trough drawdown along a path is 7.4%, and there is a 13% probability of a drawdown worse than 20% at some point in the decade. Planning for the median while ignoring the path is how institutions get caught needing liquidity at the worst moment - which brings the argument back to why that 20% public sleeve exists.

9.3 Machine learning: tagging deal flow automatically

Sovereign investors publish hundreds of free-text announcements a year. Tagging each to a sector by hand is **slow and inconsistent** between analysts. We trained a text classifier - TF-IDF word and character n-

Figure 13: Classifier confusion matrix. Source: author's model.

The honest measure of the model is the hold-out test: twelve real Mubadala announcements that appear nowhere in training. The classifier got 92% of them right.

The single failure is the most useful result. The model tagged 'Mubadala agrees to sell minority stake in CoolIT data centre liquid cooling to Ecolab' as Industrials rather than Technology. It is not obviously wrong. CoolIT makes physical cooling hardware for data centres, it's both. The lesson is not that the classifier needs more training data; it is that a single-label data model is the wrong shape for a portfolio where the most interesting assets sit between sectors. The fix is multi-label tagging, and that is a data-design decision, not a modelling one.

9.4 Do the chosen comparables match how the market groups companies?

Analysts pick comparables by industry label. Markets price business characteristics. We clustered the nineteen-company peer universe on size and valuation features, choosing the number of clusters by silhouette score rather than by eye. GlobalFoundries' nearest neighbours in that space turn out to be ON Semiconductor and Agilent Technologies - not TSMC or UMC. The market treats it as a mid-cap specialty manufacturer, which is a useful corrective to a peer set assembled purely from the word 'foundry'.

10. Conclusions, risks and limitations

10.1 What the analysis supports

1. **Mubadala is running a concentrated, illiquid, self-funding book, and that is a coherent strategy for a permanent-capital sovereign investor.** The HHI of 2,734 and the 58% private-plus-alternatives weighting are features, not bugs. The recycling ratio near 1.0 shows the model works without new shareholder capital.
2. **Technology is the organising theme, expressed through four platforms rather than one bucket.** Semiconductors, AI infrastructure, AI-enabled healthcare and energy-transition software all recur, and the CoolIT exit demonstrates the theme being realised rather than merely accumulated.
3. **The liquid sleeve is insurance, and the insurance costs about one point of volatility.** Naming the price converts a governance argument into a quantified trade-off.
4. **Valuation discipline differs sharply by asset, and the differences are the useful output.** GlobalFoundries is priced for execution; OMV is fairly valued with a deteriorating dividend cushion; WHOOP is priced for a decade of 35% growth; Mubadala Capital's fee annuity is the only holding whose value does not depend on the direction of markets.

10.2 Risks to the strategy

Risk	Why it matters here	Where it shows up in this report
Exit-market closure	A recycling ratio near 1.0 means deployment depends on realisations. If exit markets freeze, deployment must fall or the balance sheet must lever.	Section 4
Concentration in private assets	58% of the book is marked infrequently. Reported volatility understates true economic volatility.	Sections 3.2 and 9.1
Execution risk in semiconductors	The GlobalFoundries share price requires a margin expansion of more than 20 percentage points. Any slippage is repriced directly.	Section 5.2
Commodity and dividend risk	OMV's dividend cover has fallen to 1.3x. A cut would hit both the income and the equity value of a 24.9% stake.	Section 6.3
Venture-stage mispricing	WHOOP's entry multiple leaves no room for a growth disappointment; the bear case is an 89% loss.	Section 7.2
Geopolitical and regulatory	Semiconductor, AI and energy assets are precisely the sectors most exposed to export controls, screening regimes and subsidy politics.	Sections 3.3 and 5

10.3 Limitations - what this report can't tell you

- **There is no position-level portfolio.** Mubadala does not publish one. The twenty tracked holdings are a curated, source-tagged sample, not the whole book, and the sector percentages describe that sample rather than the group's true economic exposure.
- **Deal totals are floors.** Ten of nineteen logged transactions disclose no value. The US\$44.4 billion figure is what is public, not what was spent.
- **Capital-market assumptions are the author's.** Expected returns, volatilities and correlations behind the optimiser and the simulation are not Mubadala's. Change them and the conclusions about efficiency change with them.
- **All forward assumptions are estimates.** Growth rates, margins, discount rates and terminal values in every DCF are judgements. The sensitivity tables in the workbook exist so a reader can substitute their

OWN.

- **Two case studies value private companies.** WHOOP and Mubadala Capital are frameworks built on stated assumptions. They are designed to expose their own inputs, not to produce a defensible price.
- **Nothing here is investment advice**, and the author holds no position in any security mentioned.

10.4 Future suggestions I could improve on:

- Replace the manual holdings dataset with an automated pipeline that ingests Mubadala's newsroom RSS feed, runs the classifier, and refreshes the warehouse nightly.
- Move from single-label to multi-label sector tagging, which the CoolIT failure showed is the real constraint.
- Extend the peer clustering to a full sector universe and use it to select comparables systematically rather than by hand.
- Add a currency layer: OMV is a euro asset, GlobalFoundries a dollar asset, and the reporting currency is the dirham. The FX translation effect on reported AUM is not modelled here and is not trivial.
